

# SYMMETRIC PERIODIC ORBITS AND UNIRULED REAL LIOUVILLE DOMAINS

URS FRAUENFELDER AND OTTO VAN KOERT

**ABSTRACT.** A real Liouville domain is a Liouville domain together with an exact anti-symplectic involution. We call a real Liouville domain uniruled if there exists an invariant finite energy plane through every real point. Asymptotically an invariant finite energy plane converges to a symmetric periodic orbit. In this note we work out a criterion which guarantees uniruledness for real Liouville domains.

## 1. INTRODUCTION

A **real Liouville domain**  $(W, \lambda, \varrho)$  is a triple consisting of a Liouville domain  $(W, \lambda)$  and an exact anti-symplectic involution  $\varrho \in \text{Diff}(W)$ , i.e. a map  $\varrho$  satisfying

$$\varrho^2 = \text{id}, \quad \varrho^* \lambda = -\lambda.$$

If we restrict  $\varrho$  to the boundary  $\partial W$  of the Liouville domain  $W$  we get a real contact manifold, meaning a contact manifold together with an involution under which the contact form is anti-invariant. If  $R$  denotes the Reeb vector field on  $\partial W$ , then  $R$  is anti-invariant under  $\varrho$  as well, i.e.

$$\varrho^* R = -R.$$

If  $T > 0$  and  $v \in C^\infty([0, T], \partial W)$  is a  $T$ -periodic orbit for  $R$ , then  $v_\varrho \in C^\infty([0, T], \partial W)$  defined as

$$v_\varrho(t) = \varrho(v(T - t))$$

is a  $T$ -periodic orbit as well.

**Definition 1.1.** A  $T$ -periodic orbit  $v \in C^\infty([0, T], \partial W)$  is called **symmetric** if it satisfies  $v = v_\varrho$ .

Symmetric periodic orbits play a prominent role in the restricted three body problem [B] as well as in the Seifert conjecture on brake orbits [Se].

The Weinstein conjecture asserts that on every closed contact manifold the Reeb flow admits a periodic orbit. Affirmative answers to this conjecture can be obtained in various cases by taking advantage of the interplay between holomorphic curves and closed Reeb orbits [HV, LT, L, We]. To examine this connection in the real case we introduce the notion of a uniruled real Liouville domain. Note that for a real Liouville domain  $(W, \lambda, \varrho)$  the Liouville vector field  $X$  defined by the equation  $\iota_X d\lambda = \lambda$  is invariant under  $\varrho$  and therefore  $\varrho$  extends to the completion  $V$  of  $W$ . By abuse of notation we will use the symbols  $\lambda$  and  $\varrho$  also for the extensions to  $V$ . If we choose on  $V$  an SFT-like almost complex structure anti-invariant under  $\varrho$ , then  $\varrho$  induces an involution of finite energy planes on  $V$ . Inspired by the paper of McLean [McL] we make the following definition.

**Definition 1.2.** A real Liouville domain  $(W, \lambda, \varrho)$  is called **(real) uniruled** if for every anti-invariant SFT-like complex structure  $J$  on the completion  $(V, \lambda, \varrho)$  there exists an invariant finite energy plane of SFT-energy less than or equal to 1 through every point on the Lagrangian submanifold  $\text{Fix}(\varrho) \subset V$ .

The asymptotic behavior of finite energy planes as studied in [HWZ1, HWZ2, HWZ3, Mo] immediately implies

---

2010 *Mathematics Subject Classification.* Primary 34C25, 32Q65, 53D05, 53D10.

*Key words and phrases.* Symmetric periodic orbits, real symplectic manifolds, uniruled.

**Theorem 1.3.** *Assume that  $(W, \lambda, \varrho)$  is a uniruled real Liouville domain. Then there exists a symmetric periodic orbit of the Reeb vector field  $R$  on  $\partial W$  of period less than or equal to 1.*

*Remark 1.4.* If one requires that the SFT-energy of the invariant finite energy planes in Definition 1.2 is less than or equal to a constant  $\kappa > 0$  instead of being less than or equal to 1, the period of the symmetric Reeb orbit in Theorem 1.3 can be estimated from above by the constant  $\kappa$ . However, we can always scale  $\lambda$  to  $\frac{1}{\kappa}\lambda$  so that one does not gain anything by considering this more general notion.

The purpose of this note is to provide a condition which guarantees uniruledness for a real Liouville domain. For this we embed the real Liouville domain into a closed symplectic manifold and use Gromov-Witten theory on this ambient manifold. One could use Welschinger's invariants ("real Gromov-Witten theory") as used for instance in [Wel], but we will argue indirectly. Let us now explain the properties we require on the ambient manifold.

Assume that  $(M, \omega)$  is a closed symplectic manifold that satisfies the Bohr-Sommerfeld condition, namely the cohomology class represented by the symplectic form is integral in the sense that the class  $[\omega]$  lies in the image of  $H^2(M; \mathbb{Z})$  in  $H^2(M; \mathbb{R})$ . We suppose in addition that  $[\omega]$  is **primitive** in the sense that for every  $k > 1$  the cohomology class  $\frac{1}{k}[\omega]$  is not integral.

**Definition 1.5.** We say that a symplectic hypersurface  $\Sigma \subset M$  is **primitive** if  $[\Sigma]$  is Poincaré dual to  $[\omega]$ .

*Remark 1.6.* If  $H^2(M; \mathbb{Z})$  is torsion free, this notion is unambiguous. If  $H^2(M; \mathbb{Z})$  has torsion, the class  $[\omega] \in H_{dR}^2(M)$  does not uniquely determine an integral cohomology class. In this latter case, we mean that  $[\Sigma]$  is Poincaré dual to  $[\omega]$  when regarded as a real homology class in  $H_{2n-2}(M; \mathbb{R})$ .

Denote by  $h: \pi_2(M) \rightarrow H_2(M; \mathbb{Z})$  the Hurewicz homomorphism.

**Definition 1.7.** We say that a class  $A \in \text{im}(h)$  is **decomposable** if there exist classes  $B, C \in \text{im}(h)$  satisfying

$$A = B + C, \quad \langle [\omega], B \rangle > 0, \quad \langle [\omega], C \rangle > 0.$$

We say that  $A$  is **indecomposable** if it is not decomposable.

**Definition 1.8.** A **decoration**  $\mathcal{D} = (\Sigma, A, S)$  of  $(M, \omega)$  is a triple consisting of a primitive symplectic hypersurface  $\Sigma \subset M$ , an indecomposable homology class  $A \in H_*(M)$  and a submanifold  $S \subset \Sigma$  satisfying the following two requirements

- (i):  $A \circ [\Sigma] = 1$ .
- (ii): The Gromov-Witten invariant  $GW_A([S], [p])$  is odd, where  $[p]$  is the homology class of a point.

We refer to the triple  $(M, \omega, \mathcal{D})$  as a **decorated symplectic manifold**.

*Remark 1.9.* By Gromov-Witten invariants we mean the variant defined in [MS2], and for this we insist that  $S$  is a submanifold rather than a general cycle.

*Remark 1.10.* Note that for a decoration  $\mathcal{D} = (\Sigma, A, S)$  we have

$$\langle [\omega], A \rangle = PD([\omega]) \circ A = [\Sigma] \circ A = 1$$

so that each holomorphic sphere contributing to the Gromov-Witten invariant  $GW_A([S], [p])$  has symplectic area equal to 1.

**Definition 1.11.** Assume that  $(M, \omega, \mathcal{D})$  is a decorated symplectic manifold with decoration  $\mathcal{D} = (\Sigma, A, S)$ . An **anti-decorating involution**  $\rho: M \rightarrow M$  is an anti-symplectic involution satisfying the following conditions

- (i): Both  $\Sigma$  and  $S$  are invariant under  $\rho$ .
- (ii):  $\rho^*A = -A$ .

A **decorated real symplectic manifold**  $(M, \omega, \mathcal{D}, \rho)$  is a quadruple consisting of a decorated symplectic manifold  $(M, \omega, \mathcal{D})$  together with an anti-decorating involution  $\rho$ .

**Definition 1.12.** Assume that  $(W, \lambda, \varrho)$  is a real Liouville domain and  $(M, \omega, \mathcal{D}, \rho)$  is a decorated real symplectic manifold. An **embedding of a real Liouville domain into a decorated symplectic manifold**

$$\varepsilon: (W, \lambda, \varrho) \rightarrow (M, \omega, \mathcal{D}, \rho)$$

is an embedding  $\varepsilon: W \rightarrow M \setminus \Sigma$  satisfying

$$d\lambda = \varepsilon^* \omega, \quad \varrho = \varepsilon^* \rho.$$

A **Christmas tree** is a quadruple  $(W, \lambda, \rho, \varepsilon)$  consisting of a real Liouville domain  $(W, \lambda, \rho)$  and an embedding  $\varepsilon: (W, \lambda, \rho) \rightarrow (M, \omega, \mathcal{D}, \rho)$  into a decorated real symplectic manifold.

The main result of this paper is

**Theorem 1.13.** *Assume that  $(W, \lambda, \rho, \varepsilon)$  is a Christmas tree satisfying  $b_1(W) = 0$ . Then  $(W, \lambda, \rho)$  is real uniruled.*

Combining Theorem 1.13 with Theorem 1.3 we obtain the following Corollary.

**Corollary 1.14.** *Assume that  $(W, \lambda, \rho, \varepsilon)$  is a Christmas tree satisfying  $b_1(W) = 0$ . Then there exists a symmetric periodic orbit of period less than or equal to 1 for the Reeb flow on  $\partial W$ .*

## 2. DEFINITIONS AND NOTIONS OF SYMPLECTIC FIELD THEORY (SFT)

By a **real symplectic manifold** we mean a triple  $(M, \omega, \rho)$  where  $(M, \omega)$  is a symplectic manifold and  $\rho \in \text{Diff}(M)$  is an **anti-symplectic involution**, so

$$\rho^2 = \text{id}, \quad \rho^* \omega = -\omega.$$

A **Liouville domain** is a compact exact symplectic manifold  $(W, \omega = d\lambda)$  with a global Liouville vector field, defined by  $i_X \omega = \lambda$ , such that the boundary is smooth and convex, meaning that the Liouville vector field  $X$  points outward at the boundary.

The boundary of a Liouville domain carries a natural cooriented contact structure. Indeed, the Liouville condition implies that  $\alpha := \lambda|_{\partial W}$  is a positive contact form on  $\partial W$ , so  $\alpha \wedge (d\alpha)^{n-1} > 0$ . The hyperplane distribution defined by

$$\xi = \ker \alpha \subset T\partial W$$

is called the **contact structure** and the vector field  $R$  on  $\partial W$  defined by the equations

$$\iota_R \alpha = 1, \quad \iota_R d\alpha = 0$$

is called the **Reeb vector field**.

The following procedure can be used to complete a Liouville domain  $W$  into a so-called **Liouville manifold**, which has cylindrical ends instead of convex boundary components. For each boundary component  $C$  of  $\partial W$ , we attach the positive end of a **symplectization**, given by the symplectic manifold  $([0, \infty[ \times C, d(e^t \alpha))$ , to  $W$  along  $C$ . The Liouville vector field on the cylindrical end is

$$X = \frac{\partial}{\partial t}$$

After this process we obtain a complete Liouville manifold, which we will denote by  $(V, \lambda)$

An almost complex structure  $J$  on a complete Liouville manifold  $V$  is called **compatible** with the symplectic form  $\omega = d\lambda$  if  $\omega(\cdot, J\cdot)$  is a Riemannian metric. An  $\omega$ -compatible almost complex structure  $J$  is called **SFT-like** if it satisfies the following conditions

- (1)  $J$  preserves the hyperplane distribution  $\xi$  on  $\partial W \subset V$ .
- (2) On  $\partial W$  it rotates the Liouville vector field into the Reeb vector field in the sense that  $JX = R$  and  $JR = -X$ .
- (3) On the cylindrical end  $\partial W \times [0, \infty[$  the almost complex structure is invariant under the Liouville flow  $\varphi_X^t$  for  $t \in [0, \infty)$ .

Pick an SFT-like almost complex structure  $J$  on  $V$  and assume that  $w: (\mathbb{C}, i) \rightarrow (V, J)$  is a  $J$ -holomorphic plane. We now explain how to define the energy of  $w$ . This will be a variation of the Hofer energy. Choose a small  $\delta > 0$ , indicating the size of a collar neighborhood of  $\partial W$ , and define

$$\Lambda := \left\{ \varphi \in C^\infty([-\delta, \infty[, [0, 1]) : \varphi' \geq 0, \varphi'|_{[-\delta, 0]} = 0 \right\}.$$

For  $\varphi \in \Lambda$  define a 1-form  $\lambda_\varphi \in \Omega^1(V)$  by

$$\lambda_\varphi(y) = \begin{cases} \varphi(r)\alpha(x) & \text{if } y = (x, r) \in \partial W \times [0, \infty[ \\ \varphi(0)\lambda(y) & \text{if } y \in W \end{cases}$$

and abbreviate  $\omega_\varphi = d\lambda_\varphi$ . The **Hofer energy** or **SFT energy** of  $w$  is then defined as

$$E(w) = \sup_{\varphi \in \Lambda} \int_{\mathbb{C}} w^* \omega_\varphi \in [0, \infty].$$

The holomorphic plane  $w$  is called a **finite energy plane** if it satisfies

$$0 < E(w) < \infty.$$

We also have the following non-real version of uniruledness, somewhat different from [McL].

**Definition 2.1.** We call a Liouville domain  $(W, \lambda)$  **uniruled** if for every SFT-like almost complex structure  $J$  on its completion  $(V, \lambda)$  there exists a finite energy plane through every point of  $V$ .

### 3. EXAMPLES OF CHRISTMAS TREES

In this section we will discuss some examples of Christmas trees. An interesting example concerns the canonical contact form and structure on the unit cotangent bundle of a sphere,  $(T^*S^n, \lambda_{can}, \rho)$ , which can be embedded as a real Liouville manifold into the projective quadric with various anti-symplectic involutions  $\rho$ . We will check that the projective quadric can be decorated by computing a suitable Gromov-Witten invariant. Real Liouville structures on  $T^*S^2$  include the regularized, planar circular restricted three body problem [AFvKP], which has one anti-symplectic involution, and the Hill's lunar problem, which has two commuting anti-symplectic involutions.

Before we verify the decoration requirements for the quadric, we start by giving the following basic lemma.

**Lemma 3.1.** *Let  $(M, \omega, \mathcal{D} = (\Sigma, A, B))$  be a decorated symplectic manifold with anti-decorating involution  $\rho$ . Then  $M - \nu_M(\Sigma)$  carries the structure of a real Liouville domain, where  $\nu_M(\Sigma)$  denotes a tubular neighborhood of  $\Sigma$  in  $M$ .*

*Proof.* We first show that  $W := M - \nu_M(\Sigma)$  is an exact symplectic manifold. For this, consider the long exact sequence of the pair in cohomology,

$$H^2(M, W) \xrightarrow{j_\Sigma^*} H^2(M) \xrightarrow{j_W^*} H^2(W).$$

By Corollary 11.2 of [MiS], the cohomology ring  $H^*(M, W)$  is canonically isomorphic to the cohomology ring  $H^*(\nu_M(\Sigma), \nu_M(\Sigma)_0)$ , associated with the normal bundle of  $\Sigma$ . Here  $\nu_M(\Sigma)_0$  denotes the normal bundle of  $\Sigma$  with its zero-section removed. Thus the Thom class  $u \in H^2(\nu_M(\Sigma), \nu_M(\Sigma)_0)$  corresponds to a class  $u'$  in  $H^2(M, W)$ . As the homology class  $[\Sigma]$  is Poincaré dual to  $[\omega]$  (over the reals), it follows that  $j_\Sigma^* u'$  equals  $[\omega]$  by Problem 11-C from [MiS]. By exactness of the long exact sequence of the pair, we see  $j_W^*[\omega] = j_W^* \circ j_\Sigma^* u' = 0$ , so there exists a 1-form  $\lambda \in \Omega_W^1$  such that  $d\lambda = \Omega := \omega|_W$ .

We now show that we can choose a real Liouville form  $\tilde{\lambda}$ , i.e.  $\rho^* \tilde{\lambda} = -\tilde{\lambda}$ . Since  $d\lambda = \Omega$ , and  $\rho^* \Omega = -\Omega$  we see that there exists a closed 1-form  $\mu$  such that

$$\rho^* \lambda = -\lambda + \mu.$$

Since  $\lambda = \rho^* \circ \rho^* \lambda = \lambda - \mu + \rho^* \mu$ , we see that  $\mu = \rho^* \mu$ . Define  $\tilde{\lambda} := \lambda - \frac{1}{2}\mu$ . Then  $\rho^* \tilde{\lambda} = \rho^* \lambda - \frac{1}{2} \rho^* \mu = -\lambda + \frac{1}{2}\mu = -\tilde{\lambda}$ . Hence  $(W, \tilde{\lambda}, \rho)$  is the desired real Liouville domain.  $\square$

**3.1. Smooth quadrics in projective space.** We define a **quadric** in projective space as the zeroset of a non-zero homogeneous quadratic polynomial. Note that a homogeneous quadratic polynomial can always be written as  $p(z) = z^t B z$ , where  $B$  is a symmetric matrix. By Sylvester's theorem, we can assume that  $B$  is diagonal. We then easily see

**Lemma 3.2.** *A quadric is smooth if and only if  $B$  has maximal rank.*

We have the following identification of the smooth projective quadric with an oriented Grassmannian.

**Lemma 3.3.** *The smooth projective quadric given by*

$$Q^n = \{[z_0, \dots, z_{n+1}] \in \mathbb{CP}^{n+1} \mid \sum_j z_j^2 = 0\}$$

*is diffeomorphic to the symmetric space  $Gr^+(2, n) \cong \mathrm{SO}(n+2)/\mathrm{SO}(2) \times \mathrm{SO}(n)$ . Furthermore,  $\mathrm{SO}(n+2)$  acts transitively via biholomorphisms.*

*Proof.* For the first part, we exhibit the diffeomorphism

$$\begin{aligned} Gr^+(2, n+2) &\longrightarrow Q^n \\ span(x, y) &\longmapsto x + iy. \end{aligned}$$

Here  $x, y \in \mathbb{R}^{n+2}$  form an orthonormal basis of the 2-plane they span. We use that  $\sum_j z_j^2 = \|x\|^2 - \|y\|^2 + 2i\langle x, y \rangle$ . To see that  $\mathrm{SO}(n+2)$  acts by biholomorphisms, just observe that

$$\begin{aligned} \mathrm{SO}(n+2) \times Q^n &\longrightarrow Q^n \\ (A, [x + iy]) &\longmapsto [Ax + iAy] = [A(x + iy)]. \end{aligned}$$

□

By an **affine quadric** we mean the zeroset of a non-zero quadratic polynomial in  $\mathbb{C}^{n+1}$ . Away from possible singular points an affine quadric inherits a symplectic structure as a complex submanifold of a Kähler manifold. It is well-known, see [MS1, Exercise 6.20], that a smooth affine quadric is symplectomorphic to  $T^*S^n$  with its canonical symplectic structure.

**Lemma 3.4.** *There is a symplectomorphism*

$$\begin{aligned} (V = \{(z_0, \dots, z_n) \in \mathbb{C}^{n+1} \mid \sum_j z_j^2 = 1\}, \omega_0) &\longrightarrow (T^*S^n, \omega_{can}) \subset T^*\mathbb{R}^{n+1} \\ z = x + iy &\longmapsto \left(\frac{x}{\|x\|}, \|x\|y\right). \end{aligned}$$

The singular affine quadric appearing in the following lemma is also of interest.

**Lemma 3.5.** *The symplectization of  $(ST^*S^n, \lambda_{can})$  is symplectomorphic to*

$$V_0 = \{(z_0, \dots, z_n) \in \mathbb{C}^{n+1} \mid \sum_j z_j^2 = 0\} \setminus \{0\}.$$

*In addition, the standard complex structure  $i$  is an SFT-like complex structure for the symplectization.*

**3.2. Naive Gromov-Witten invariants of quadrics.** We consider a smooth quadric  $Q^n$  given as the zero locus of the symmetric bilinear form  $B$ . The Lefschetz hyperplane theorem implies that for  $n > 2$ , we have  $H_2(Q^n; \mathbb{Z}) \cong \mathbb{Z}$ , see [MS1, Example 4.27]. Moreover, this homology group is generated by a line  $L$ , by which we mean a map of the form  $[\lambda : \mu] \in \mathbb{CP}^1 \mapsto \lambda p + \mu q$ , where  $p, q \in Q^n \subset \mathbb{CP}^{n+1}$  (so  $B(p, p) = B(q, q) = 0$ ) and  $B(p, q) = 0$ . The quadric  $Q^2$  in 4-dimensions is diffeomorphic to  $S^2 \times S^2$ , so  $H_2(Q^2; \mathbb{Z}) \cong \mathbb{Z}^2$ , and there are two types of lines, distinguished by their homology class. We will equip  $Q^n$  with its natural complex structure  $J_0$ .

Let  $Hol(J_0, [L])$  denote the space of  $J_0$ -holomorphic maps from  $\mathbb{CP}^1$  to  $Q^n$  representing the homology class  $[L]$ . Write  $\mathcal{M}(J_0, [L])$  for the moduli space of  $J_0$ -holomorphic curves with homology class  $[L]$ . We have

$$\mathcal{M}(J_0, [L]) = Hol(J_0, [L]) / Aut(\mathbb{CP}^1).$$

We will compute some Gromov-Witten invariants by “naive counting”, [RT]. To show that this works, we need to establish regularity of  $J_0$ .

**3.3. Moduli space and regularity.** Let  $L$  be a line on a smooth projective quadric with primitive homology class  $[L] \in H_2(Q^n; \mathbb{Z})$ . We linearize the Cauchy-Riemann equations at a parametrization of  $L$  given by  $u : \mathbb{CP}^1 \rightarrow Q^n$ .

**Lemma 3.6.** *The linearized operator at  $u$  is surjective. In particular, the space of holomorphic maps  $\text{Hol}(J_0, [L])$  in  $Q^n$  is a smooth manifold of dimension  $\dim \text{Hol}(J_0, [L]) = 2n + 2n$ .*

We give two arguments for this statement.

**3.3.1. Regularity via sheafs and splitting of the normal bundle.** In the language of sheafs, triviality of the cokernel is equivalent to vanishing of the sheaf cohomology group  $H^1(L, \mathcal{T}Q^n|_L)$  (cf. the statement of Riemann-Roch). We have the short exact sequence of sheafs

$$0 \longrightarrow \mathcal{T}L \longrightarrow \mathcal{T}Q^n|_L \longrightarrow \nu_L \longrightarrow 0,$$

where  $\nu_L$  is the sheaf of germs of holomorphic sections of the normal bundle of  $L$ . A piece of the corresponding long exact sequence in cohomology looks like

$$H^1(L, \mathcal{T}L) \longrightarrow H^1(L, \mathcal{T}Q^n|_L) \longrightarrow H^1(L, \nu_L).$$

It is a well-known classical fact that  $H^1(\mathbb{CP}^1, \mathcal{O}(k)) = 0$  for  $k \geq -1$  (a generalization of this formula is known as the Bott formula, see [OSS, Chapter 1]), so we see directly that  $H^1(L, \mathcal{T}L) = 0$  as  $\mathcal{T}L \cong \mathcal{O}(2)$ . For the normal bundle, note that a line  $L$  in a smooth quadric  $Q^n$  is always contained in a tower of smooth quadrics of the form

$$L \subset Q^2 \subset Q^3 \subset \dots \subset Q^n.$$

The normal bundle  $\nu_{Q^k}(Q^{k-1})$  is isomorphic to  $\mathcal{O}(1)$ , and the normal bundle  $\nu_{Q^2}(L)$  is trivial, so  $\nu_L$  splits as

$$\mathcal{O}(1)^{n-2} \oplus \mathcal{O}.$$

By the earlier mentioned Bott formula  $H^1(L, \nu_L) \cong H^1(\mathbb{CP}^1, \mathcal{O}(1))^{\oplus n-2} \oplus H^1(\mathbb{CP}^1, \mathcal{O}) = 0$ , so we conclude that  $H^1(L, \mathcal{T}Q^n|_L) = 0$ .

**3.3.2. Regularity via holomorphic transitive actions.** Lemma 3.3 tells us that we have a holomorphic transitive action on  $Q^n$ , so by [MS2, Proposition 7.4.3], every holomorphic sphere is regular, and the claim of the Lemma follows.

**3.4. Lines through a point.** Now consider the evaluation map

$$\begin{aligned} ev : \text{Hol}(J_0, [L]) \times_{\text{Aut}(\mathbb{CP}^1)} \mathbb{CP}^1 &\longrightarrow Q^n \\ [u, z] &\longmapsto u(z). \end{aligned}$$

By Sard’s theorem we find a regular value  $p$  of  $ev$ , and in fact, since  $SO(n+2)$  acts transitively on  $Q^n$ , every value is regular. Define the moduli space of lines through  $p$  as  $\mathcal{M}_p = ev^{-1}(p)$ .

Geometrically, we can describe  $\mathcal{M}_p$  as follows. If  $L = pq$  is a line through  $p$  and  $q$  that is completely contained in  $Q^n$ , then  $B(\lambda p + \mu q, \lambda p + \mu q) = 0$  for all  $[\lambda : \mu] \in \mathbb{CP}^1$ . This gives a quadratic equation in  $\lambda$  and  $\mu$ , which should vanish identically, so by looking at the coefficients we find

$$B(p, p) = 0, \quad B(p, q) = 0, \quad B(q, q) = 0.$$

As  $p$  and  $q$  lie on  $Q^n$ , we automatically have  $B(p, p) = 0 = B(q, q)$ . The remaining equation defines a hyperplane in  $\mathbb{CP}^{n+1}$ , namely the “geometric tangent plane”

$$P := \{z \in \mathbb{CP}^{n+1} \mid B(p, z) = 0\}.$$

Since every line through  $p$  intersects the quadric at infinity, given by  $Q_\infty = \{z = [z_0 : \dots : z_n : 0] \mid z \in Q^n\}$ , we can identify the moduli space of lines through  $p$  with  $\mathcal{M}_p = Q_\infty \cap P$ .

To obtain a Gromov-Witten invariant, we will consider lines through  $p$  going through an additional cycle  $C$ . First define

$$\begin{aligned} ev : Hol(J_0, [L]) \times_{\text{Aut}(\mathbb{CP}^1)} \mathbb{CP}^1 \times \mathbb{CP}^1 &\longrightarrow Q^n \times Q^n \\ [u; z_1, z_2] &\longmapsto (u(z_1), u(z_2)). \end{aligned}$$

A dimension count tells us that  $C$  should be a 2-cycle if we want  $ev^{-1}(\{p\} \times C)$  to consist of points. Hence we take  $C$  to be a line (which is of course a smooth submanifold) in  $Q_\infty$  which transversely intersects  $\mathcal{M}_p$ , regarded as a subset in  $Q_\infty$ , in a point  $q_0$ . We get a unique element in  $\mathcal{M}(J_0, [L]) \times_{\text{Aut}(\mathbb{CP}^1)} \mathbb{CP}^1 \times \mathbb{CP}^1$  which maps to  $(p, q) \in Q^n \times Q^n$ , and we may represent this element by  $(u; [0 : 1], [1 : 0])$ .

To check that the evaluation map is transverse to  $\{p\} \times C$ , we observe that  $C$  is transverse to the set

$$Cone(p, \mathcal{M}_p) = \{q \in Q^n \mid q \text{ lies on the line from } p \text{ to some point in } \mathcal{M}_p \subset Q_\infty \subset Q^n\}$$

First we show that vectors of the form  $(v, 0) \in T_p Q^n \times T_{q_0} Q^n$  lie in the image of  $T_{[u; [0:1], [1:0]]} ev$ . Indeed, put  $p_s := \exp_p(sv)$ , and follow the above procedure to define  $\mathcal{M}_{p_s}$ . For small  $s$  we find a unique intersection point  $q_s := \mathcal{M}_{p_s} \cap C$ . Therefore we find a variation  $(u_s, [0 : 1], [1 : 0])$  which is mapped to  $(p_s, q_s)$  under  $ev$ . Note here that the curve  $q_s$  is tangent to  $C$ .

To see that a vector of the form  $(0, w)$  also lies in the image of  $T_{[u; [0:1], [1:0]]} ev$ , we first note that we can assume that  $w$  lies in the tangent space to  $Cone(p, \mathcal{M}_p)$  since the normal to  $Cone(p, \mathcal{M}_p)$  is tangent to  $C$ . The curve  $\tilde{q}_s := \exp_p(sw)$  lies in  $Cone(p, \mathcal{M}_p)$ , so by definition of this cone, we find a line from  $p$  to  $\tilde{q}_s$ . Hence we find a variation  $(u_s, [0 : 1], [1 : z_s])$  which maps to  $(p, \tilde{q}_s)$ .

We conclude

**Proposition 3.7.** *The 2-point Gromov-Witten invariant  $GW_{[L]}^{Q^n}([p], [C])$  equals 1.*

We remind the reader that  $H_2(Q^2) \cong \mathbb{Z} \oplus \mathbb{Z}$ , and there are two distinct homology classes  $[L]$  represented by a line in this case. We collect the above results in the following theorem.

**Theorem 3.8.** *The projective quadric  $Q^n$  admits a decoration by  $\mathcal{D} = (Q^{n-1}, [L], C)$ , where  $[L]$  is the homology class of a line and  $C$  is the submanifold described above.*

*Remark 3.9.* It is clear that the projective quadric has many anti-symplectic involutions. For instance, we can compose conjugation with swapping coordinates.

#### 4. EXISTENCE OF INVARIANT CURVES

Complex conjugation on  $\mathbb{CP}^1$  defines an anti-symplectic involution  $R_0 : \mathbb{CP}^1 \rightarrow \mathbb{CP}^1$ , namely

$$\rho_0[z_0 : z_1] = [\bar{z}_0 : \bar{z}_1].$$

Now pick an  $\omega$ -compatible almost complex structure  $J$  on  $TM$  which is anti-invariant under  $\rho$ , so

$$\rho^* J = -J.$$

Denote the space of parametrized  $J$ -holomorphic maps from  $\mathbb{CP}^1$  to  $M$  by  $Hol(J)$ . We define an involution on this space,

$$\begin{aligned} I : Hol(J) &\longrightarrow Hol(J) \\ u &\longmapsto \rho \circ u \circ \rho_0. \end{aligned}$$

Now we will write the fixed point locus of this involution as

$$Hol(J)^\rho = \{u \in Hol(J) : I(u) = u\}.$$

Take a point  $p \in M$ , a submanifold  $S \subset M$  and a spherical homology class  $A \in \text{im}(h)$ , where  $h : \pi_2(M) \rightarrow H_2(M; \mathbb{Z})$  is the Hurewicz homomorphism, and define

$$Hol(J; (S, p; A)) = \{u \in Hol(J) : u(\nu) \in S, u(\sigma) = p, [u] = A\}$$

where  $\nu = [1 : 0] \in \mathbb{CP}^1$  is the “north-pole” and  $\sigma = [0 : 1] \in \mathbb{CP}^1$  is the “south-pole”. Note that both the north- and the south-pole lie on the real part  $\mathbb{RP}^1 = \text{Fix}(\rho_0) \subset \mathbb{CP}^1$ . The parametrization

is not yet fully determined by just two marked points, so we still have a  $\mathbb{C}^*$ -action on this space. Later, we will mod out by this action.

Suppose now that  $S$  is invariant under  $\rho$ , that the point  $p$  lies in the Lagrangian  $L = \text{Fix}(\rho)$ , and that the homology class  $A$  is anti-invariant, so  $\rho_*A = -A$ . Then the space  $\text{Hol}(J, (S, p; A))$  is invariant under the involution  $I$  and we set

$$\text{Hol}^\rho(J, (S, p; A)) = \text{Hol}(J, (S, p; A)) \cap \text{Hol}(J)^\rho.$$

If  $\Sigma \subset M$  is a symplectic submanifold we will write  $\mathcal{J}(\Sigma, \rho)$  for the space of all  $\omega$ -compatible almost complex structures on  $M$ , which are anti-invariant under the anti-symplectic involution  $\rho$  and which restrict on  $\Sigma$  to an  $\omega|_\Sigma$ -compatible almost complex structure such that  $\Sigma$  becomes a  $J$ -holomorphic submanifold of  $M$ . The main result of this section is the following theorem.

**Theorem 4.1.** *Assume that  $(M, \omega, \mathcal{D}, \rho)$  is a decorated real symplectic manifold with decoration  $\mathcal{D} = (\Sigma, A, S)$ . Then for every point  $p \in L \cap \Sigma^c$  and every almost complex structure  $J \in \mathcal{J}(\Sigma, \rho)$  the moduli space  $\mathcal{M}_J^\rho(S, p; A) = \text{Hol}^\rho(J, (S, p; A))/\mathbb{C}^*$  is nonempty.*

The proof of Theorem 4.1 needs some preparation. We first recall from [MS2, Section 2.5] that a holomorphic curve  $u: \mathbb{CP}^1 \rightarrow M$  is called **multiply covered** if there exists a holomorphic curve  $v: \mathbb{CP}^1 \rightarrow M$  and a holomorphic map  $\varphi: \mathbb{CP}^1 \rightarrow \mathbb{CP}^1$  satisfying

$$u = v \circ \varphi, \quad \deg(\varphi) > 1.$$

If a curve is not multiply covered, it is called **simple**.

**Lemma 4.2.** *A holomorphic curve  $u \in \text{Hol}(J)$  is simple if and only if  $I(u)$  is simple.*

*Proof.* First suppose that  $u$  is simple and suppose that  $v \in \text{Hol}(J)$  and  $\varphi: \mathbb{CP}^1 \rightarrow \mathbb{CP}^1$  is a holomorphic map such that

$$I(u) = v \circ \varphi.$$

By using that  $I$  is an involution, we compute

$$u = I^2(u) = I(v\varphi) = \rho v \varphi \rho_0 = \rho v \rho_0 \rho_0 \varphi \rho_0 = I(v) \circ (\rho_0 \varphi \rho_0).$$

Since  $u$  is simple by assumption we conclude that

$$\deg(\varphi) = \deg(\rho_0 \varphi \rho_0) = 1$$

and therefore  $I(u)$  is simple as well. This proves the "only if" part and the "if" part follows again from the fact that  $I^2(u) = u$ .  $\square$

We now need that fact that  $\text{Aut}(\mathbb{CP}^1) = \text{PSL}_2(\mathbb{C})$ .

**Definition 4.3.** A simple holomorphic curve  $u \in \text{Hol}(J)$  is called a **pseudo-fixed point** if there exists  $\varphi \in \text{PSL}_2(\mathbb{C})$  such that  $I(u) = u \circ \varphi$ . It is called a **fixed point** if  $\varphi$  is the identity, i.e.  $I(u) = u$ .

*Remark 4.4.* It follows from [MS2, Proposition 2.5.1] that a simple holomorphic curve has no nontrivial automorphisms. Therefore the map  $\varphi$  for a pseudo-fixed point is uniquely determined.

**Lemma 4.5.** *Assume that  $u \in \text{Hol}(J)$  is a pseudo-fixed point, so that  $I(u) = u\varphi$  for some  $\varphi \in \text{PSL}_2(\mathbb{C})$ . Then  $\varphi\rho_0: \mathbb{CP}^1 \rightarrow \mathbb{CP}^1$  is an anti-holomorphic involution.*

*Proof.* That  $\varphi\rho_0$  is anti-holomorphic is clear. To check that it is an involution we compute

$$u = I^2(u) = I(u\varphi) = \rho u \varphi \rho_0 = \rho u \rho_0 \rho_0 \varphi \rho_0 = I(u) \rho_0 \varphi \rho_0 = u \varphi \rho_0 \varphi \rho_0.$$

Since  $u$  is simple by assumption it follows from [MS2, Proposition 2.5.1] that  $u$  has no nontrivial automorphisms so that

$$(\varphi\rho_0)^2 = \text{id}.$$

This finishes the proof of the lemma.  $\square$

We abbreviate by  $\mathcal{I} \subset \text{Diff}(\mathbb{CP}^1)$  the space of anti-holomorphic involutions of  $\mathbb{CP}^1$ .

**Proposition 4.6.** *The space  $\mathcal{I}$  has two connected components.*

*Proof.* We first show that  $\mathcal{I}$  is diffeomorphic to the space

$$\mathcal{J} = \{[A] \in PSL_2(\mathbb{C}) : [\bar{A}] = [A^{-1}]\}$$

where for  $A \in SL_2(\mathbb{C})$  we denote by  $[A]$  its equivalence class in the projectivization  $PSL_2(\mathbb{C})$  and by  $\bar{A}$  the complex conjugate of the matrix  $A$ . We define a map

$$\Phi: \mathcal{I} \rightarrow \mathcal{J}, \quad \psi \mapsto \psi\rho_0.$$

To check that this map is well defined we first note that  $\psi\rho_0: \mathbb{CP}^1 \rightarrow \mathbb{CP}^1$  is a biholomorphism so that  $\psi\rho_0 = [A] \in PSL_2(\mathbb{C})$ . Now we compute using the fact that  $\rho_0$  as well as  $\psi$  are involutions

$$[\bar{A}] = \rho_0(\psi\rho_0)\rho_0 = \rho_0\psi = \rho_0^{-1}\psi^{-1} = (\psi\rho_0)^{-1} = [A^{-1}].$$

This proves that  $\Phi$  is well defined. To show that it is a diffeomorphism we construct its inverse as follows

$$\Psi: \mathcal{J} \rightarrow \mathcal{I}, \quad \varphi \mapsto \varphi\rho_0.$$

That  $\Psi$  is inverse to  $\Phi$  is an immediate consequence from the fact that  $\rho_0$  is an involution. It therefore just remains to check that  $\Psi$  is well defined, i.e. that  $\varphi\rho_0$  is actually an involution. This follows from the following computation

$$(\varphi\rho_0)^2 = \varphi(\rho_0\varphi\rho_0) = \varphi\varphi^{-1} = \text{id}.$$

This proves that  $\mathcal{I}$  and  $\mathcal{J}$  are diffeomorphic.

In view of the diffeomorphism established above we are left with showing that  $\mathcal{J}$  has two connected components. We rewrite  $\mathcal{J}$  first as the quotient

$$\mathcal{J} = \tilde{\mathcal{J}}/\mathbb{Z}_2$$

where

$$\tilde{\mathcal{J}} = \tilde{\mathcal{J}}_+ \cup \tilde{\mathcal{J}}_-$$

with

$$\tilde{\mathcal{J}}_{\pm} = \left\{ A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{C}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \pm \begin{pmatrix} \bar{d} & -\bar{b} \\ -\bar{c} & \bar{a} \end{pmatrix} \right\}$$

and the  $\mathbb{Z}_2$ -action identifies  $A$  with  $-A$ . Note that both  $\tilde{\mathcal{J}}_+$  and  $\tilde{\mathcal{J}}_-$  are invariant under the  $\mathbb{Z}_2$ -action. If  $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \tilde{\mathcal{J}}_+$ , then this is equivalent that

$$a = \bar{d}, \quad b, c \in i\mathbb{R}, \quad |a|^2 - bc = 1.$$

Hence we can identify  $\tilde{\mathcal{J}}_+$  with the hyperboloid of one sheet

$$\mathcal{H}_1 = \{(x_1, x_2, x_3, x_4) \in \mathbb{R}^4 : x_1^2 + x_2^2 + x_3^2 - x_4^2 = 1\}$$

via the map

$$\mathcal{H}_1 \rightarrow \tilde{\mathcal{J}}_+, \quad (x_1, x_2, x_3, x_4) \mapsto \begin{pmatrix} x_1 + ix_2 & i(x_3 + x_4) \\ i(x_3 - x_4) & x_1 - ix_2 \end{pmatrix}.$$

The hyperboloid of one sheet  $\mathcal{H}_1$  is connected and therefore we conclude that  $\tilde{\mathcal{J}}_+$  and  $\tilde{\mathcal{J}}_+/\mathbb{Z}_2$  are connected as well.

It remains to show that  $\tilde{\mathcal{J}}_-/\mathbb{Z}_2$  is connected as well. If  $A = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \tilde{\mathcal{J}}_-$ , then this is equivalent that

$$a = -\bar{d}, \quad b, c \in \mathbb{R}, \quad |a|^2 - bc = 1.$$

Hence we can identify  $\tilde{\mathcal{J}}_-$  with the hyperboloid of two sheets

$$\mathcal{H}_2 = \{(x_1, x_2, x_3, x_4) \in \mathbb{R}^4 : -x_1^2 - x_2^2 - x_3^2 + x_4^2 = 1\}$$

via the map

$$\mathcal{H}_2 \rightarrow \tilde{\mathcal{J}}_-, \quad (x_1, x_2, x_3, x_4) \mapsto \begin{pmatrix} x_1 + ix_2 & x_3 + x_4 \\ x_3 - x_4 & -x_1 + ix_2 \end{pmatrix}.$$

The pullback of the involution on  $\tilde{\mathcal{J}}_-$  to  $\mathcal{H}_2$  is given by  $x \mapsto -x$ . This involution interchanges the two sheets of  $\mathcal{H}_2$  and therefore  $\tilde{\mathcal{J}}_-/\mathbb{Z}_2$  is connected. This finishes the proof of the Proposition.  $\square$

Keeping the notation from the proof of Proposition 4.6, we abbreviate the two connected components of the space  $\mathcal{I}$  by

$$\mathcal{I}_\pm := \Psi(\mathcal{J}_\pm), \quad \mathcal{J}_\pm := \tilde{\mathcal{J}}_\pm/\mathbb{Z}_2.$$

An example of a holomorphic involution in  $\mathcal{I}_+$  is the involution  $\rho_0: [z_0 : z_1] \mapsto [\bar{z}_0 : \bar{z}_1]$  and an example of an anti-holomorphic involution in  $\mathcal{I}_-$  is the antipodal map  $\sigma_0: [z_0 : z_1] \mapsto [\bar{z}_1 : -\bar{z}_0]$ . Note that the fixed point set of  $\rho_0$  is topologically a circle, while  $\sigma_0$  has no fixed points. Since the topological type of the fixed point set only depends on the connected component of  $\mathcal{I}$  we conclude the following lemma.

**Lemma 4.7.** *Each anti-holomorphic involution in  $\mathcal{I}_-$  acts freely, while the fixed point set of each involution in  $\mathcal{I}_+$  is topologically a circle.*

**Definition 4.8.** A pseudo-fixed point  $u \in \text{Hol}(J)$  satisfying  $I(u) = u\varphi$  is called of **type I** if  $\varphi \in \mathcal{J}_+$ . Otherwise  $u$  is called of **type II**, meaning that  $\varphi \in \mathcal{J}_-$ .

**Proposition 4.9.** *Assume that  $u \in \text{Hol}(J)$  is a pseudo-fixed point of type I. Then there exists  $\psi \in \text{PSL}_2(\mathbb{C})$  such that  $u \circ \psi$  is a fixed point.*

**Proof:** Since  $u$  is a pseudo-fixed point we have  $I(u) = u\varphi$  for  $\varphi \in \text{PSL}_2(\mathbb{C})$  and because  $u$  is of type I we have  $\varphi\rho_0 \in \mathcal{I}_+$ . By Lemma 4.7 we know that the fixed point set of  $\varphi\rho_0$  is topologically a circle. Identify  $\mathbb{CP}^1$  with the two dimensional sphere  $S^2 = \{x \in \mathbb{R}^3 : \|x\| = 1\}$  via stereographic projection. We first claim that the fixed point set  $\text{Fix}(\varphi\rho_0)$  is actually a small circle, namely the intersection of  $S^2$  with an affine plane in  $\mathbb{R}^3$ . To see this pick three points on  $\text{Fix}(\varphi\rho_0)$ . These three points uniquely determine a small circle. Since  $\varphi$  and  $\rho_0$  as well map small circles to small circles we conclude that this small circle is fixed under  $\varphi\rho_0$  and hence has to agree with  $\text{Fix}(\varphi\rho_0)$ . This shows that  $\text{Fix}(\varphi\rho_0)$  is a small circle.

Since the group  $\text{PSL}_2(\mathbb{C})$  acts transitively on small circles we conclude that there exists  $\psi \in \text{PSL}_2(\mathbb{C})$  satisfying

$$\psi(\text{Fix}(\rho_0)) = \text{Fix}(\varphi\rho_0).$$

This implies that

$$\text{Fix}(\varphi\rho_0) = \text{Fix}(\psi\rho_0\psi^{-1}).$$

By analyticity we conclude that

$$\varphi\rho_0 = \psi\rho_0\psi^{-1}.$$

Using this equality we compute

$$I(u\psi) = \rho u \psi \rho_0 = \rho u \rho_0 \rho_0 \psi \rho_0 = u \varphi \rho_0 \psi \rho_0 = u \psi \rho_0 \psi^{-1} \psi \rho_0 = u \psi.$$

Hence  $u\psi$  is a fixed point. This finishes the proof of the proposition.  $\square$

**Proposition 4.10.** *Assume that  $\Sigma \subset M$  is a complex  $\rho$ -invariant hypersurface and  $u \in \text{Hol}(J)$  is a pseudo-fixed point satisfying  $[u] \circ [\Sigma] = 1$  and  $\text{im}(u) \not\subset \Sigma$ . Then  $u$  is of type I.*

**Proof:** Since  $[u] \circ [\Sigma] = 1$ , the image of  $u$  is not contained in  $\Sigma$  and  $\Sigma$  is complex we deduce from positivity of intersections that  $\#u^{-1}(\Sigma) = 1$ , i.e. there exists  $w_0 \in \mathbb{CP}^1$  such that

$$u^{-1}(\Sigma) = \{w_0\}. \quad (4.1)$$

Since  $u$  is a pseudo-fixed point there exists  $\varphi \in \text{PSL}_2(\mathbb{C})$  such that  $I(u) = u\varphi$ . We compute using the  $\rho$ -invariance of  $\Sigma$

$$u\varphi\rho_0(w_0) = \rho u \rho_0 \rho_0(w_0) = \rho u(w_0) \in \rho\Sigma = \Sigma.$$

We deduce from (4.1) that

$$\varphi\rho_0(w_0) = w_0.$$

In particular, the fixed point set of the anti-holomorphic involution  $\varphi\rho_0$  is not empty. We conclude with Lemma 4.7 that  $\varphi\rho_0 \in \mathcal{I}_+$  or equivalently that  $\varphi \in \mathcal{J}_+$  and therefore  $u$  is a pseudo-fixed point of type I. This proves the proposition.  $\square$

**Definition 4.11.** Assume  $u \in \text{Hol}(J)$ . A point  $w \in \mathbb{CP}^1$  is called a  $\rho$ -**injective point** of  $u$  if

$$du(w) \neq 0, \quad u^{-1}\{u(w), \rho u(w)\} = \{w\}.$$

**Lemma 4.12.** Assume that  $u \in \text{Hol}(J)$  is a simple holomorphic map which is not a pseudo-fixed point. Then the complement of the set of  $\rho$ -injective points of  $u$  is finite.

*Proof.* Denote by  $Z_\rho \subset \mathbb{CP}^1$  the complement of the set of  $\rho$ -injective points. Abbreviate further

$$Z = \{w \in \mathbb{CP}^1 : du(w) = 0 \text{ or } \#u^{-1}(u(w)) > 1\}$$

the set of non-injective points of  $u$  and

$$\mathcal{T} = \{(w_0, w_1) \in \mathbb{CP}^1 \times \mathbb{CP}^1 : u(w_0) = \rho u(w_1), w_0 \neq w_1\}.$$

Consider the map

$$\pi : \mathcal{T} \rightarrow \mathbb{CP}^1, \quad \pi(w_0, w_1) = w_0.$$

Note that

$$Z_\rho = Z \cup \text{im}(\pi).$$

Since  $u$  is simple the set  $Z$  is finite by positivity of intersection, see [MS2, Theorem E.1.2.]. It therefore suffices to show that the set  $\mathcal{T}$  is finite as well. To see that first note that by Lemma 4.2  $I(u)$  is simple as well. Therefore it follows from [MS2, Corollary 2.5.3] that

$$\text{im}(u) \neq \text{im}(I(u)).$$

Hence by positivity of intersection

$$\#\{(w_0, w_1) \in \mathbb{CP}^1 \times \mathbb{CP}^1 : u(w_0) = I(u)(w_1)\} < \infty.$$

Note that

$$\begin{aligned} \#\{(w_0, w_1) \in \mathbb{CP}^1 \times \mathbb{CP}^1 : u(w_0) = I(u)(w_1)\} &= \\ \#\{(w_0, w_1) \in \mathbb{CP}^1 \times \mathbb{CP}^1 : u(w_0) = \rho u(w_1)\} & \end{aligned}$$

We deduce that

$$\#\mathcal{T} < \infty.$$

This finishes the proof of the Lemma.  $\square$

We are now ready to prove the main result of this section.

*Proof of Theorem 4.1:* We argue by contradiction and assume that there exists  $J \in \mathcal{J}(\Sigma, \rho)$  such that the moduli space  $\mathcal{M}_J^\rho(S, p; A) = \text{Hol}^\rho(J', (S, p; A))/\mathbb{C}^*$  is empty. Since  $A$  is indecomposable there is no bubbling and therefore it follows from compactness of holomorphic curves that there exists an open neighborhood  $\mathcal{J}_0 \subset \mathcal{J}(\Sigma, \rho)$  of  $J$  such that  $\mathcal{M}_{J'}^\rho(S, p; A) = \emptyset$  for every  $J' \in \mathcal{J}_0$ . In view of Proposition 4.9 there is therefore no pseudo-fixed point of type I in the space of holomorphic maps  $\text{Hol}^\rho(J', (S, p; A))$  for every  $J' \in \mathcal{J}_0$ . Together with Proposition 4.10 the assumptions of the theorem show that there does not exist a pseudo-fixed point of type II either and therefore there are no pseudo-fixed points at all in  $\text{Hol}(J', (S, p; A))$  for every  $J' \in \mathcal{J}_0$ .

Furthermore,  $A$  is indecomposable, so each holomorphic curve  $u$  representing  $A$  is simple and we conclude with Lemma 4.12 that for every  $J' \in \mathcal{J}_0$  every holomorphic map  $u \in \text{Hol}(J', (S, p; A))$  has  $\rho$ -injective points. Transversality arguments, see [MS2, Section 6.2, Section 6.3], then show that there exists an open and dense subset  $\mathcal{J}_0^{\text{reg}} \subset \mathcal{J}_0$  such that for every  $J' \in \mathcal{J}_0^{\text{reg}}$  the Gromov-Witten invariant  $GW_A([S], [p])$  can be obtained as the signed count of points in the moduli space  $\mathcal{M}(J', (S, p; A)) = \text{Hol}(J', (S, p; A))/\mathbb{C}^*$ . Since this Gromov-Witten invariant is odd by assumption we conclude that

$$1 = GW_A([S], [p]) \bmod 2 = \#\mathcal{M}_{J'}(S, p; A) \bmod 2.$$

However, the moduli space  $\mathcal{M}_{J'}(S, p; A)$  is invariant under the involution  $I$  which has no fixed points by construction. Therefore the cardinality of the moduli space  $\mathcal{M}_{J'}(S, p; A)$  has to be even. This contradiction finishes the proof of the theorem.  $\square$

## 5. THE PROOF

The basic idea to prove Theorem 1.13 is to embed a real Liouville domain into a decorated symplectic manifold making it into a Christmas tree. By hanging up some Christmas balls, or in other words taking holomorphic spheres through  $\Sigma$  and a given real point  $p$ , and applying a stretching construction we obtain an invariant finite energy plane through every point in the real locus.

We need some lemmas to prepare the Christmas tree for the Christmas balls.

**Lemma 5.1.** *Let  $(M, \omega, \mathcal{D} = (\Sigma, A, S))$  be a decorated symplectic manifold with an anti-symplectic involution  $\rho$ , and assume that  $(W_0, \lambda_0, \rho|_{W_0})$  is a real Liouville domain that embeds into the interior of  $M - \nu(\Sigma)$  for some  $\rho$ -invariant neighborhood  $\nu(\Sigma)$  of  $\Sigma$ . Suppose in addition that  $b_1(W_0) = 0$ .*

*Then  $W_1 := M - \nu(\Sigma)$  carries the structure of a real Liouville domain  $(W_1, \lambda_1, \rho|_{W_1})$  such that  $(W_0, \lambda_0, \rho|_{W_0})$  is a real Liouville subdomain in the sense that  $\lambda_1|_{W_0} = \lambda_0$ .*

*Proof.* Since we will need a cutoff function, we first extend  $\lambda_0$  to a neighborhood of  $W_0$ . By Lemma 3.1,  $W_1 := M - \nu(\Sigma)$  is a real Liouville domain  $(W_1, \tilde{\lambda}_1, \rho)$ . As  $\omega = d\tilde{\lambda}_1 = d\lambda_0$  on a neighborhood of  $W_0$ , we see that  $\tilde{\lambda}_1 - \lambda_0$  is closed, and as  $b_1(W) = 0$ , we find a function  $f$  on a neighborhood of  $W_0$  such that  $\lambda_0 = \tilde{\lambda}_1 - df$ . It follows directly that  $\rho^*df = -df$ . If  $\rho^*f \neq -f$ , then we replace  $f$  by  $\frac{1}{2}(f - \rho^*f)$ .

Find a  $\rho$ -invariant cutoff function  $g$  such that  $g \equiv 1$  on  $W_0$ , and such that  $g \equiv 0$  on the complement of a neighborhood of  $W_0$ . Then  $\lambda_1 = \tilde{\lambda}_1 - d(gf)$  has the desired properties.  $\square$

**Lemma 5.2.** *Let  $(M, \omega, \mathcal{D} = (\Sigma, A, S))$  be a decorated symplectic manifold, and assume that  $(W_0, \lambda_0, \rho|_{W_0})$  is a real Liouville domain that embeds into the interior of  $M - \nu(\Sigma)$  for some  $\rho$ -invariant neighborhood  $\nu(\Sigma)$  of  $\Sigma$ . Suppose in addition that  $b_1(W_0) = 0$ . Let  $J$  be an almost complex structure on  $M$  that is compatible with  $\omega$ , and SFT-like near  $\partial W_0$ .*

*Assume that  $u : \mathbb{CP}^1 \rightarrow M$  is a  $J$ -holomorphic sphere through a point  $p \in W_0$  such that  $[u] \circ [\Sigma] = 1$ . Then the component  $C$  of  $u^{-1}(W_0)$  containing  $z_0$  with  $u(z_0) = p$  satisfies the following:*

- $C$  is diffeomorphic to a disk.
- $\int_C u|_C^* \omega = \int_C u|_C^* d\lambda_0 \leq 1$ . In particular, the SFT energy of  $u|_C$  is bounded from above by 1.

*Proof.* After possibly shifting the boundary  $\partial W_0$  a little, we can assume that  $u^{-1}(\partial W_0)$  consists of finitely many circles. Let  $C$  denote the component of  $u^{-1}(W_0)$  containing  $z_0$ . We claim that  $C$  has only one boundary component. To see why, note that if  $C$  has more than one boundary component, then there is a connected component of  $\tilde{C} := \mathbb{CP}^1 - \text{int}(C)$  with the properties

- $\tilde{C}$  shares a boundary component with  $C$ .
- $u(\tilde{C})$  does not intersect  $\nu(\Sigma)$ , and is contained in  $M - \text{int}(W_0)$ .

To see that the latter condition can be imposed, we observe that  $u$  intersects  $\Sigma$  only once, and we also use that  $\mathbb{CP}^1$  has genus 0.

Now apply the previous lemma to see that  $M - \nu(\Sigma)$  carries the structure of a real Liouville domain  $(W_1, \lambda_1)$  with real Liouville subdomain  $(W, \lambda)$ . This allows us to compute the energy of  $\tilde{C}$  via Stokes' theorem,

$$E(u|_{\tilde{C}}) = \int_{\tilde{C}} u|_{\tilde{C}}^* \omega = \int_{\tilde{C}} du|_{\tilde{C}}^* \lambda_1 = \int_{\partial \tilde{C}} u|_{\tilde{C}}^* \lambda_1 < 0.$$

The last inequality holds, because the orientation induced by the outward pointing normal is minus the one induced by the Reeb vector field; one can see this by using that  $J$  is SFT-like near  $\partial W_0$ . Since the energy of the holomorphic curve  $u|_{\tilde{C}}$  is positive, this is a contradiction, so we conclude that  $C$  has one boundary component. It follows directly that  $C$  is diffeomorphic to a disk. The claimed energy estimate is now also clear since  $\int_{\mathbb{CP}^1} u^* \omega = 1$ .  $\square$

We will now apply a stretching argument to obtain an invariant finite energy plane. This is illustrated in Figure 1. Let  $X$  denote the Liouville vector field on  $M - \Sigma$ . Take a point  $p \in W_0$ ,

**Figure 1.** Hanging up Christmas balls (holomorphic spheres) in a Christmas tree

and for  $\tau \in \mathbb{R}_{\geq 0}$  define  $p_\tau$  by following the Liouville flow backwards,  $p_\tau = Fl_{-\tau}^X(p)$ . Define the stretched Liouville domain  $W_0^\tau$  by

$$W_0^\tau := (W_0, \omega = d\lambda_0) \cup_{\partial} ([0, \tau] \times \partial W_0, d(e^t \lambda_0|_{\partial W_0})).$$

Choose a compatible complex structure  $J_\tau$  on  $W_0^\tau$  that is SFT-like on  $[0, \tau] \times \partial W_0$ . We choose this sequence  $J_\tau$  such that it is a constant sequence of complex structures when restricted to  $W_0$ . Since the map  $x \mapsto Fl_\tau^X(x)$  provides a symplectic deformation from  $W_0$  to  $W_0^\tau$ , we can pull back  $J_\tau$  to a complex structure on  $W_0$  that is SFT-like near the boundary. Extend this  $J_\tau$  to a compatible complex structure  $\tilde{J}_\tau$  for  $(M, \omega)$ .

With Lemma 5.2 applied to an invariant holomorphic sphere obtained with Theorem 4.1, we find a  $\tilde{J}_\tau$ -holomorphic disk

$$\tilde{u}_\tau : \tilde{C}_\tau \subset \mathbb{CP}^1 \longrightarrow W_0$$

going through  $p_\tau$ , and with boundary on  $\partial W_0$ . We now stretch the Liouville domain  $W_0$  to a Liouville domain  $W_0^\tau$  using the above deformation. This deformation also gives us a  $J_\tau$ -holomorphic curve

$$u_\tau : C_\tau \longrightarrow W_0^\tau$$

going through  $p$ . As the Hofer energy of  $\tilde{u}_\tau$  is bounded by 1, so is the Hofer energy of  $u_\tau$ .

Denote the norm induced by  $\omega_\tau(\cdot, J_\tau \cdot)$  by  $\|\cdot\|_\tau$ . By rescaling the domain we can ensure that  $\max_{z \in C_\tau} \|du_\tau\|_\tau = 1$ ; we need to rescale the disk  $C_\tau$  for this, but we will continue to write  $C_\tau$  for this rescaled disk. Since  $p$  lies in  $W_0$  and the boundary of the disk,  $u_\tau(\partial C_\tau)$ , lies on  $\{\tau\} \times \partial W_0$ , we see directly that radius for the disk  $C_\tau$  has to be at least  $\tau$  by a very crude estimate using  $\max_{z \in C_\tau} \|du_\tau\|_\tau = 1$ . Taking the limit  $\tau \rightarrow \infty$ , we find a convergent subspace, and obtain a map

$$u_\infty : \mathbb{C} \rightarrow W_0^\infty,$$

where  $W_0^\infty$  is the completion of  $W_0$ . As the Hofer energy of  $u_\infty$  is bounded from above by 1, we conclude that  $u_\infty$  is the desired finite energy plane through  $p \in W_0$ .

This stretching construction also implies the well-known corollary, see also [L].

**Corollary 5.3.** *Let  $(W, \lambda)$  be a Liouville domain admitting an embedding into a decorated symplectic manifold  $(M, \omega, \mathcal{D})$ . Suppose that  $b_1(W) = 0$ . Then  $W$  is uniruled. Furthermore, there exists a periodic orbit of period less than or equal to 1 for the Reeb flow on  $\partial W$ .*
